Report

Pharmacy_portal_db.sql- This was the first thing I worked on, creating all the tables using phpMyAdmin. Then I created the stored procedures, medical inventory view, and the trigger using the same method.

PharmacyDatabase.php- Other than changing the password to "" I don't remember needing to change any database connection settings.

Created the addMedication, addUser, and getUserDetails functions within PharmacyDatabase.php

Created login.php, I was intending to create a system where users can register as either a pharmacist or patient but I couldn't figure out how to do it. I made it so if a user who was not registered logged in it would automatically create a new account for them and hash the password.

I got stuck on addPrescription.php. I thought the AddOrUpdateUser procedure and AfterPrescriptionInsert trigger would just work when I added a new prescription through the website but it didn't and I couldn't figure out why.
